Searchable sets, Dubuc-Penon compactness, Omniscience Principles, and the Drinker Paradox

> Martín Escardó Joint work with Paulo Oliva

Theory lab lunch, School of CS, Birmingham, 26 Jan 2010

Abstract

1. A number of contenders for logical notion of compactness coincide.

- 2. Need the axiom of choice AC(X, 2) for one equivalence.
- 3. This is related to the topopological notion of total-separatedness.

Introduction

- 1. Higher-type computability.
- 2. Searchable sets must be compact, Tychonoff theorem.
- 3. Proof theory, Peirce translation, double negation shift.

4. Work by Dubuc and Penon in topos theory.

Logical notions of compactness

- 1. Drinker paradox.
- 2. Principle of omniscience.
- 3. Searchable sets.
- 4. Dubuc-Penon compactness.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Drinker paradox.

In every pub there is a person a such that if a drinks then everybody drinks.

A set X satisfies the *drinker paradox* iff

$$\forall p \colon X \to \Omega \; \exists a \in X \left(p(a) \implies \forall x \in X(p(x)) \right).$$

In classical logic, a set satisfies this condition if and only if it is non-empty.

Boolean drinker paradoxes

X satisfies the boolean drinker paradox iff

$$\forall p \colon X \to 2 \; \exists a \in X(pa = 0 \implies \forall x \in X(px = 0)).$$

Another version: In any pub there is a person *a* such that if somebody drinks then *a* drinks:

$$\forall p \colon X \to 2 \; \exists a \in X (\exists x \in X (px = 1)) \implies pa = 1.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Searchable sets.

X is searchable iff

$$\forall p \colon X \to 2 \; \exists a \in X \left(\neg \neg \exists x \in X (px = 1) \right) \implies pa = 1.$$

Remark

1. Considered a stronger definition in computability:

 $\exists \varepsilon \colon (X \to 2) \to X \quad \forall p \colon X \to 2(\neg \neg \exists x \in X(px=1)) \Longrightarrow p(\varepsilon p) = 1.$

- 2. The axiom of choice gives the stronger version from the weaker one.
- 3. AC is is validated in realizability interpretations, and provable in ML type theory.
- 4. In this note it is more natural to take the weaker definition as the official one.

Principle of omniscience.

X satisfies the principle of omniscience iff

$$\forall p \colon X \to 2 \ (\exists x \in X(px = 1)) \lor (\forall x \in X(px = 0)).$$

Dubuc-Penon compactness

X is Dubuc-Penon compact iff

 $\forall A \colon \Omega \ \forall B \colon X \to \Omega \ (\forall x \in X(A \lor B(x))) \implies A \lor \forall x \in X(B(x)).$

Boolean Dubuc-Penon compactness

We say that X is boolean Dubuc-Penon compact iff

 $\forall A \colon \Omega \ \forall B \colon X \to 2 \ (\forall x \in X(A \lor B(x))) \implies A \lor \forall x \in X(B(x)).$

Summary of notions

BDP_{$$\forall$$}:
 $\forall p: X \to 2 \quad \exists a \in X(pa = 0 \implies \forall x \in X(px = 0)).$
BDP _{\exists} :
 $\forall p: X \to 2 \quad \exists a \in X(\exists x \in X(px = 1)) \implies pa = 1.$
searchable:
 $\forall p: X \to 2 \quad \exists a \in X(\neg \neg \exists x \in X(px = 1)) \implies pa = 1.$
PO:
 $\forall p: X \to 2 \quad (\exists x \in X(px = 1)) \lor (\forall x \in X(px = 0)).$

Dubuc-Penon compact: $\forall A \colon \Omega \ \forall B \colon X \to \Omega \ (\forall x \in X(A \lor B(x))) \implies A \lor \forall x \in X(B(x)).$

BDP-compact: $\forall A: \Omega \ \forall B: X \to 2 \ (\forall x \in X(A \lor B(x))) \implies A \lor \forall x \in X(B(x)).$

Theorem

The following are equivalent for any inhabited set X:

- 1. X is searchable.
- 2. X is boolean Dubuc-Penon compact.
- 3. X satisfies the boolean drinker paradox.
- 4. X satisfies the principle of omniscience.

Moreover,

1. Dubuc-Penon compactness of X implies these conditions, and

2. if the axiom of choice AC(X, 2) holds then the converse is true.

Remark

1. In particular, this theorem holds in realizability over system T.

- 2. In Martin Löf type theory.
- 3. And we have developed it in Agda.

Proof structure and more details

◆□▶ ◆□▶ ◆注▶ ◆注▶ 注目 のへ(?)

- 1. If $BDP_{\forall}(X)$ then X is inhabited.
- 2. DP-compact(\emptyset).

Proof.

Considering any predicate, say p(x) = 0, we get $a \in X$ by definition.

The left disjunct of the DP-compactness conclusion $A \lor \forall x \in X(B(x))$ holds vacuosly when X is empty.

```
searchable(X) \implies BDP<sub>∃</sub>(X).
```

Proof. BDP_{\exists}(X) has a stronger premise and hence is weaker.

 $\mathsf{BDP}_{\exists}(X) \implies \mathsf{BDP}_{\forall}(X).$

Proof.

For any given $p: X \to 2$, the assumption produces $a \in X$ that satisfies $(\exists x \in X(px = 1)) \implies p(a) = 1$, and hence $p(a) = 0 \implies \forall x \in X(px = 0)$, and so $BDP_{\forall}(X)$ holds.

 $\mathsf{BDP}_\forall(X) \implies \mathsf{PO}(X).$

Proof.

For any $p: X \to 2$, the assumption produces $a \in X$ such that $p(a) = 0 \implies \forall x \in X(px = 0)$.

Because p(a) = 0 is decidable, we can reason by cases.

If it holds, then $\forall x \in X(px = 0)$.

Otherwise p(a) = 1 and hence $\exists x \in X(p(x) = 1)$.

Therefore PO(X) holds.

 $PO(X) \implies searchable(X) \text{ for } X \text{ inhabited.}$ Proof. Let $p: X \rightarrow 2$.

By PO(X), either $\exists x \in X(px = 1)$ or else $\forall x \in X(px = 0)$.

In the first case we take any *a* with pa = 1, and $\neg \neg \exists x \in X(px = 1) \implies pa = 1$ holds simply because the conclusion is true and so searchable(X) holds.

In the second case we have that $\neg \neg \exists x \in X(px = 1)$ is impossible,

and hence the implication $\neg \neg \exists x \in X(px = 1) \implies pa = 1$ holds for any $a \in X$,

which can be found by inhabitedness of X, and again searchable(X) holds.

BDP-compact(X) \implies PO(X). Proof. Let $p: X \rightarrow 2$ and define $A = \exists x \in X.(px = 1)$ and B(x) = (px = 0).

Then $A \vee B(x)$ holds for any $x \in X$.

In fact, because B(x) is decidable, we can reason by cases.

If B(x) holds, then $A \vee B(x)$.

Otherwise, px = 1 and hence A holds, and so does $A \vee B(x)$.

(日) (同) (三) (三) (三) (○) (○)

Hence $A \lor \forall x \in X(B(x))$ holds by DP-compactness of X,

which amounts to PO.

PO(X) \implies BDP-compact(X). Proof. By PO, either $\exists x \in X(\neg Bx)$ or else $\forall x \in X(Bx)$.

In the first case A holds, and hence in both cases $A \lor \forall x \in X(B(x))$ holds,

which is the conclusion of boolean DP-compactness.

If B is not decidable, then one cannot apply PO to B.

The following lemma instead applies PO to a suitable predicate constructed with the axiom of choice.

$$PO(X) \implies DP\text{-compact}(X) \text{ if } AC(X,2) \text{ holds.}$$

Proof.

Let $x \in X$ and assume that $A \vee B(x)$.

Then, reasoning by cases, there is $y \in 2$ such that $(y = 1 \implies A) \land (y = 0 \implies B(x)).$

By the axiom of choice, there is $p: X \to 2$ such that $(px = 1 \implies A) \land (px = 0 \implies B(x)).$

Now assume the premise $\forall x \in X(A \lor B(x))$ of DP-compactness.

By PO, either $\exists x \in X(px = 1)$ or else $\forall x \in X(px = 0)$.

In the first case A holds.

In the second case $\forall x \in X(B(x))$ holds.

Hence in both cases $A \lor \forall x \in X(B(x))$ holds, which is the conclusion of DP-compactness.

Remark

Hence in the absence of the axiom of choice, DP-compactness is the strongest notion, for inhabited sets, among those considered here.

Remark about AC(X, 2).

Because existential quantification over 2 is disjunction, the axiom of choice AC(X, 2) amounts to

$$(\forall x \colon X(A(x,0) \lor A(x,1))) \implies \exists p \colon X \to 2(\forall x \colon X(A(x,p(x)))).$$

Hence another way of writing AC(X, 2) is

 $A_0 \cup A_1 = X \implies \exists B_0 \subseteq A_0, B_1 \subseteq A_1(B_0 \cap B_1 = \emptyset \land B_0 \cup B_1 = X),$ considering $B_0 = p^{-1}(0)$ and $B_1 = p^{-1}(1).$

Theorem A set X is Dubuc-Penon compact if and only if

 $\forall C, B \colon X \to \Omega \ \forall x \in X(C(x) \lor B(x)) \Longrightarrow \exists x \in X(C(x)) \lor \forall x \in X(B(x)).$

Proof. (\Leftarrow) consider C(x) = A.

(⇒): Consider the proposition $A = \exists x \in X(C(x))$.

Then $\forall x \in X(C(x) \lor B(x))$ implies $\forall x \in X(A \lor B(x))$.

Thus DP-compactness transforms into $A \lor \forall x \in X(B(x))$, as required.

The axiom of choice and total separatedness

Discussion of previous work.

Totally separated sets.

X is totally separated if

$$\forall x, y \in X (\forall p \colon X \to 2(p(x) = p(y)) \implies x = y.$$

Connected sets.

X is *connected* if all maps $X \rightarrow 2$ are constant.

If X is both connected and totally separated, then it has at most one point.

Hence total separatedness can be seen as a strong notion of disconnectedness.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

(Weaker than total disconnectedness.)

Totally separated apartness relations.

To discuss a positive version of total separatedness, we consider apartness relations.

We say that an apartness relation \sharp on X is *totally separated* if

$$\forall x, y \in X(x \ \sharp \ y \implies \exists p \colon X \to 2(p(x) \neq p(y))).$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Apartness relation on a set X.

A binary relation \sharp such that

1.
$$\neg(x \ddagger x)$$
 (irreflexivity),
2. $x \ddagger y \implies y \ddagger x$ (symmetry),
3. $x \ddagger y \implies z \ddagger x \lor z \ddagger y$ (co-transitivity).

Called sharp if

$$\neg(x \ddagger y) \implies x = y.$$

Examples

- 1. The empty relation is an apartness relation that fails to be sharp but is totally separated in a trivial way,
- 2. If X has decidable equality then the negation \neq of equality is a sharp apartness relation.
- 3. The reals have a sharp apartness relation.
- 4. A sharp apartness relation on the Cantor space $2^{\mathbb{N}}$ is given by

$$\alpha \sharp \beta \iff \exists i \in \mathbb{N}(\alpha_i \neq \beta_i).$$

Moreover, this is totally separated, by considering $p(\gamma) = \gamma_i$ where *i* is a total separatedness witness.

Of course:

Lemma

If X has some totally separated, sharp apartness relation, then X is totally separated.

Proof.

Assume that $\forall p \colon X \to 2(p(x) = p(y)).$

The contra-positive of total separatedness of \sharp gives the conclusion $\neg(x \ddagger y)$,

which sharpness transforms into x = y.

The step that relates choice to total separatedness is this:

Lemma

If AC(X, 2) holds, then any apartness relation on X is totally separated.

Proof.

Assume that $x \ \sharp \ y$ and define $A(z,0) \iff z \ \sharp \ y$ and $A(z,1) \iff z \ \sharp \ x$.

Then, by co-transitivity, for every $z \in X$ there is $t \in 2$ such that A(z, t).

By AC(X, 2), there is $p: X \to 2$ such that A(z, p(z)) for all z,

which then satisfies p(x) = 0 and p(y) = 1, as required.

Any set X has an apartness relation given by

$$x \sharp_2 y \iff \exists p \colon X \to 2(p(x) \neq p(y)),$$

which is totally separated by construction.

Proof. Irreflexivity and symmetry are immediate.

To prove co-transitivity, consider $p: X \to 2$ such that $p(x) \neq p(y)$, and let $z \in Z$.

By decidability of equality on 2, either p(z) = p(y) or p(z) = p(x).

In the first case $z \not\equiv_2 x$, and in the second case $z \not\equiv_2 y$, and hence $z \not\equiv_2 x$ or $z \not\equiv_2 y$, as required.

The relation \sharp_2 is the finest apartness relation if AC(X, 2) holds.

The apartness relation \sharp_2 doesn't need to be sharp. For example, if X is connected, then \sharp_2 is empty.

Lemma

The apartness relation \sharp_2 on X is sharp if and only if X is totally separated.

Proof.

(\Leftarrow): Because $\neg(x \sharp_2 y)$ amounts to $\forall p \colon X \to 2(p(x) = p(y))$,

which total separatedness of X transforms into x = y.

 (\Rightarrow) : Lemma 2.

Sharp sets.

Say that X is sharp if it has some sharp apartness relation.

By the above lemma, any totally separated set X is sharp, with sharpness witnessed by \sharp_2 .

Putting the above together:

Theorem If AC(X, 2) holds, X is sharp if and only if it is totally separated.

Moreover, as we have seen, in this case, any sharp apartness relation is totally separated, and \sharp_2 is the finest apartness relation, and is sharp.

Relevance to Dubuc-Penon compactness.

- 1. By the above discussion, if X is connected and has a sharp apartness relation and two distinct points, then AC(X,2) fails.
- 2. The reals are not Dubuc-Penon compact in the models considered by Dubuc and Penon,.
- 3. They are boolean DP-compact in the same models because they are searchable.

4. Because these models validate connectedness of \mathbb{R} .

Concluding questions and speculative discussion.
